

The dependency graph illustrates the relationships among the primary Python modules used by the Flask application. The `app.py` module depends on `models`, `orm_queries`, and `scrape` to support database access, analysis queries, and GradCafe data collection. The `models` module uses `db_config` to obtain the environment-based PostgreSQL configuration required for database connectivity. The `orm_queries` module depends on `models` to perform database analysis using SQLAlchemy. The `scrape` module relies on `scrape_records` and `scrape_storage` to separate applicant-record processing from data-storage operations. This modular structure separates application routing, database configuration, database operations, and web scraping into distinct components, making the project easier to maintain and understand.
